Iron is needed for bacterial growth making its bioavailability an important factor in controlling infection. Blood plasma as a result carries iron tightly bound to transferrin, which is taken up by cells by endocytosing transferrin, thus preventing its access to bacteria.

Many chronic diseases are adversely affected by moderate to significant levels of iron overload. Excess iron can accelerate the aging process by catalyzing the production of radical oxygen species (free radicals) that cause harmful oxidative stress leading to cell damage, lipid peroxidation and DNA mutagenesis.

The prevalence of iron deficiency in patients with other types of cancer ranges from 29% to 46%. The main causes of iron deficiency in people with cancer are anemia of chronic disease (discussed in the Iron and Health section below) and chemotherapy-induced anemia. However, chronic blood loss and deficiencies of other nutrients (due, for example, to cancer-induced anorexia) can exacerbate iron deficiency in this population.
