Pneumatic conveying is the movement of solids through pipe using gas (usually air) as the motive force. It differs from hydraulic or slurry conveying in that the gas expands continuously along the pipe length. The flow regime in the pipe depends greatly on the ratio of solids to gas and the particle characteristics.

One of the advantages of pneumatic conveying is that moving products vertically is calculated the same as moving them horizontally--in linear feet. However, each 90-degree sweep in the system equals 20 linear feet; thus if you are moving material horizontally 110 ft and vertically 110 ft with four 90-degree sweeps, then the conveying distance is 300 ft.

Chapter Four – Pneumatic Conveying Design All pneumatic systems use pipes or ducts to transport materials on a stream of air. An air mover generates pressure or a vacuum and is located in the system at the beginning to push materials through the line or at the end to pull materials through. The basic components of a pneumatic system are:
