The stereochemistry of ten/coordinate rare/earth and transition/metal compounds is studied from the point of view of continuous shape measures (CSM) and derived tools. A total of 19 ideal ten/vertex polyhedra belonging to 12 different symmetry point groups have been considered, from which nine are retained for the description of the stereochemistries of all studied compounds.

Inorganic chemistry deals with synthesis and behavior of inorganic and organometallic compounds. This field covers chemical compounds that are not carbon-based, which are the subjects of organic chemistry.The distinction between the two disciplines is far from absolute, as there is much overlap in the subdiscipline of organometallic chemistry.It has applications in every aspect of the chemical ...

An important branch of stereochemistry is the study of chiral molecules. Stereochemistry spans the entire spectrum of organic, inorganic, biological, physical and especially supramolecular chemistry. Stereochemistry includes methods for determining and describing these relationships; the effect on the physical or biological properties these relationships impart upon the molecules in question, and the manner in which these relationships influence the reactivity of the molecules in question (...)
